Results: Provenance, Density, and Resolved Manuscript Surface

Results: Provenance, Density, and Resolved Manuscript Surface I

The generated plan enables 11 of 11 manuscript sections and fills 40 token choice(s). Category density is adjectives: 2, artifacts: 8, audiences: 4, constraints: 3, failures: 3, measures: 6, methods: 1, nouns: 5, qualities: 3, verbs: 5. The result figures are generated from the same token plan that writes the inventory table, so visual and tabular claims share one source.

The configured results moves are report token density, show resolved section coverage, bind every manuscript token to provenance, and connect the figure and inventory to the same plan. The important result is therefore not a surprising word choice; it is the survival of traceability through a complete render path. Each token row records the variable, category, selected value, section, and config pointer that produced it.

The resolved manuscript also demonstrates the intended failure boundary. If a manuscript placeholder is added without a corresponding variable, the project test suite detects it. If a figure is referenced without registry support, the output validator reports it. If a generated number lacks evidence support, the evidence registry gate reports it before the copied output stage packages deliverables.

Visualization is enabled for configured_field_matrix, section_configuration_heatmap, field_origin_summary, token_injection_flow, section_token_allocation, provenance_trace_map, quality_gate_matrix. The configured-field figures are generated from the same explicit/default path inventory written to JSON; the pipeline, allocation, provenance, and gate figures are generated from the same token plan and QA schema.
