Scope: Related Generators and Responsible Forking

Scope: Related Generators and Responsible Forking I

The exemplar is a pipeline testbed, not a natural-language quality benchmark. It covers deterministic token selection, conditional section bodies, section-title injection, provenance tables, and generated evidence artifacts. It does not evaluate semantic originality, factual truth beyond the local configuration, or reader preference.

The configured scope moves are distinguish generation from truth, limit publication claims, point to local evidence, and explain responsible forking. The closest related systems are not general-purpose chatbots but source-owned report generators, literate-programming documents, static-site data templates, and reproducible manuscript pipelines. `template_madlib` contributes a deliberately small version of that idea for research manuscripts.

Scope: Related Generators and Responsible Forking I

Publication metadata remains bounded. The local `CITATION.cff`, `.zenodo.json`, and `codemeta.json` record the declared repository and deposited identifiers when present, but those metadata do not turn the generated manuscript into empirical validation or reader-quality evidence.
