Zero-Mock Testing Policy

The repository policy prohibits mock frameworks such as `unittest.mock`, `MagicMock`, and patch decorators [@martin2008clean; @meszaros2007xunit]. A static gate rejects those imports, and a separate inventory surfaces semantic dependency-replacement patterns for review. Tests that require external services (Ollama or public networks) use explicit `pytest.mark` markers for conditional execution; deterministic network tests use real local HTTP servers. The philosophical motivation—*analogizing excessive interaction mocking to Simmons et al.'s researcher degrees of freedom* [@simmons2011falsepositive] and the preregistration remedy [@nosek2018preregistration]—is developed fully in the Zero-Mock Tradeoff discussion.

The following example, drawn from the infrastructure test suite, illustrates zero-mock compliance:

```
def test_discover_infrastructure_modules_returns_nonempty(t):
    # Real filesystem, real YAML parsing - no MagicMock and
    modules = discover_infrastructure_modules(REPO_ROOT)
    assert modules  # actual subprocesses
```
