

Data Descriptor Template: Schema, Provenance, and Release Readiness

A FAIR-style exemplar for dataset papers

1 Abstract

This exemplar demonstrates a data descriptor workflow where schema, provenance, file inventory, license, and validation gates are first-class research artifacts.

2 Methods

The descriptor validator checks required metadata, file checksums, safe file paths, field uniqueness, field-level units, category enumerations, numeric bounds, primary-key coverage, and provenance depth before publication. The project artifact generator emits a descriptor readiness report, field-constraint summary, and metadata-only release manifest so review packets can cite checksums and schema fingerprints without bundling dataset bytes into the manuscript.

3 Results

The fixture descriptor provides a small public data-package shape suitable for tests and documentation examples. The validation report is clean, the schema fingerprint is deterministic, and the generated release manifest records one checksum-bearing file, three constrained fields, and a collection-to-validation provenance chain.
