# Results: Hypotheses and Evidence

## Results: Hypotheses and Evidence I

The configuration declares 4 hypotheses about exoplanet atmospheric research. Their names, scopes, relevant phases, and scores are emitted from the knowledge-graph artifacts rather than typed into the manuscript.

# Results: Hypotheses and Evidence I

| ID | Hypothesis | Scope | Evidence score |
|---|---|---|---|
| H1 | JWST Atmospheric Characterization | observational | pending |
| H2 | Molecular Diversity Detection | chemical | pending |
| H3 | Cross-Method Consistency | methodological | pending |
| H4 | Theoretical-Observational Agreement | theoretical | pending |

## Results: Hypotheses and Evidence I

Scores are descriptive evidence summaries, not calibrated probabilities or causal effects. If the knowledge-graph stage is disabled, if a live language model is not available, or if the corpus is synthetic, the result remains **pending** or **fixture-derived**. A pending score is an honest absence of measurement; it is not a zero and must not be interpreted as support or contradiction.

# Configured questions I

- **H1: JWST atmospheric characterization.** What evidence is reported for improved characterization in the JWST-relevant phase?
- **H2: Molecular diversity detection.** Which molecules are reported, with what uncertainty and source provenance?
- **H3: Cross-method consistency.** Do independently described observational methods report compatible properties under the configured review scope?
- **H4: Theoretical-observational agreement.** How are model predictions compared with observed spectroscopic features?

## Configured questions I

These are review questions, not conclusions. Claim-level interpretation requires the claim ledger, source tier, freshness, and domain review. A fixture run can test schema, phase linkage, and serializer behavior, but cannot establish any of these hypotheses.
